

Serrations at the front end of wind turbine blades

Even wind turbines that have already been built can be retrofitted with serrations. The start-up company WTS - Wind-Tuning-Systems has developed and patented special low-noise ...

As part of a wider framework whose long-term objective is to develop more efficient and silent wind turbines, the present study focuses on the potential noise reduction benefits offered by novel, bio ...

Serrations are sawtooth structures on wind turbine rotor blades designed to reduce noise levels and enhance aerodynamic efficiency. By disrupting turbulent airflow, these serrated edges ...

Trailing edge serrations are today an established method to reduce the aeroacoustic noise from wind turbine blades. In this paper, a brief introduction to the aerodynamic and acoustic...

To assess the impact of serrated blades on operational performance, the rotational speed and power output of the wind turbine with different structure were simulated and both compared, as shown in ...

A more detailed study on real wind turbines focusing on load analysis at different parts of the machine should be done to clarify the impact of the trailing-edge serrations on the loads and lifetime of a real ...

To this end, modern wind turbine blades are sometimes provided with serrations along the blade trailing edges, in an effort to reduce blade trailing edge noise and/or to improve wind...

Wind turbine blades have serrated edges to boost aerodynamic efficiency and diminish noise. The serrations disrupt turbulent air flow, reducing drag and tonal noise caused by vortices. By ...

Improve the noise emission of your turbines by installing serrations. Noise regulations force many operators to run their turbines in a noise-reduced mode especially at night.

The influence of the trailing-edge serrations on an operating wind turbine has been quantified in terms of total loads and energy production. The power curves with and without the ...
